

Market Pulse — Feature Readout

11 features shipped 2026-04-29 · <https://market-pulse-mef.fly.dev/>

Shipped this session

1. Earnings reaction stats

Ticker detail view

For each stock, computes avg gap %, avg same-day close, avg 5-day return, and **fade-back rate** (% of past ~8 earnings where same-day close moved $\geq 50\%$ back toward prior close). Tells you whether a name is a consistent post-print fader ($>60\%$) or a trender ($<30\%$). Refreshed nightly for tickers that just reported.

2. Trade replay vs playbook

Trade Journal → each closed trade → *Replay button*

Renders the entry/exit window with three pinned vertical lines: **green** = your entry, **yellow** = your exit, **purple** = where the playbook would have exited. Shows the realized return delta with a verdict: "you beat the playbook by X%" or "playbook would've kept Y% more — the rule that would've fired: ...".

3. Portfolio risk dashboard

Trade Journal, above *Open Positions*

Aggregate exposure across all open trades: total notional, total stop-out risk in \$ and % of account, long/short split. Warns when total risk $>6\%$ of account, when notional exceeds account (leverage check), when 3+ trades are all on one side, or when 3+ are all the same setup.

4. News headlines per signal

Ticker detail view

Top 4 yfinance headlines with publisher and relative age, cached 30 min. Lets you confirm "is this gap really earnings, or is it M&A / FDA / analyst day?" without opening another tab.

5. Setup conflict detector

Combined signals table

When a ticker is flagged by both a long-side scanner (Momentum/Reversal) AND a short-side scanner (Caution/Fade) on the same day, surfaces a banner listing the conflicted tickers and adds a  column per row. The two playbooks disagree → don't trade it without resolving why.

6. Persistent user prefs

Schema + sizing calculator

New JSON prefs column on the users table. Account size, risk %, and daily-loss-cap settings now save automatically when you change them and reload across sessions instead of resetting to defaults.

7. Liquidity / Avg \$-Volume column

All signals tables

Each scanner now returns $\text{avg_dollar_vol} = \text{price} \times \text{avg_volume_30d}$. Renders as a colored column: **RED** below \$5M (thin tape, hard to short — HTB locate is rough), **YELLOW** below \$25M, grey above. Stops you from accidentally shorting illiquid names.

8. Walk-forward backtest folds

Backtest tab

When "Apply exit playbook" is on, a slider lets you split the lookback window into N (1–6) equal time folds. Backtest runs on each fold separately and shows per-fold trades / win rate / avg return / profit factor in a small table. Stable PF across folds = robust rules; wildly varying = overfit to one regime.

9. Tunable Fade playbook params

Backtest tab → "Tune Fade playbook" expander

When backtesting Fade with the playbook on, six sliders expose the exit rules: full-target %, partial-trim %, against-position trim %, stop ATR multiplier, target ATR multiplier, time-stop days. Tweak → re-run → see profit factor change. Combined with #8, this turns the playbook from intuition into rules that demonstrably work on out-of-sample data.

10. Daily loss cap + loss-streak cooldown

Trade Journal, top of page

Two behavioral guardrails. **(a)** If today's realized + unrealized P&L drops below your account-loss threshold (default 3%, configurable in the sizing calculator), banners up "■ Daily loss cap hit — stop entering new trades." **(b)** If the last 3 closed trades all lost money, banners up "■ 3-trade losing streak — halve size on next entry or skip until you see an A+ setup."

11. Stacked price + RSI + volume chart

Ticker detail view

Replaced the three independent charts with one `make_subplots` figure: candles + MAs on top (62%), RSI in the middle (19%), volume on the bottom (19%), all sharing the x-axis. A vertical eye-line through any date maps to all three panels simultaneously — stockcharts.com layout, instant updates.

Most consequential

#9 + #8 — turn the playbook from a hunch into measurable, regime-stable rules.

#2 — turns every closed trade you've ever taken into a learning data point.

#10 — addresses the behavioral failure modes no signal can fix.

#1 — finally makes the catalyst tag *quantitative* — a 75% fade-back stock is a different setup than a 20% one, even though both wear the same ■ EARNINGS badge.
